ECE 405/ECE 511 Error Control Coding

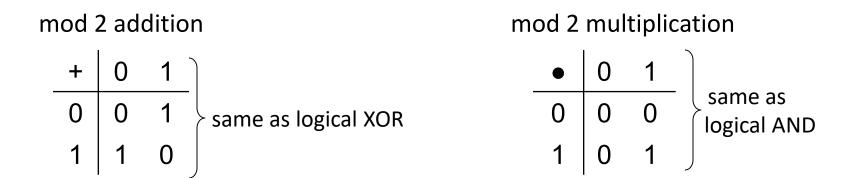

Binary Linear Block Codes

Basic Concept

- The key idea is to encode a message by adding redundant data or parity to the message.
- If the message is corrupted, the redundancy in the encoded message added at the transmitter can be used for error detection and/or correction at the receiver.
- Linear codes are the most important class of error correcting codes
 - simple description
 - nice properties
 - easy encoding
 - conceptually easy decoding

Modular Arithmetic

- With binary codes, modulo 2 arithmetic is used.
- A number mod 2 is obtained by dividing it by 2 and taking the remainder.
- For example, $3 \equiv 1 \mod 2$ and $4 \equiv 0 \mod 2$.

Vector Space

- Set of *n*-tuples over an alphabet A
 n-dimensional vector space V_n
- Example: binary *n*-tuples of length $5 V_5$
 - 5-dimensional vector space $A = \{0, 1\}$

Vector Space Operations

vector addition scalar multiplication

11001

11001	$a \bullet v$, $a \in A$
+ <u>10011</u> 01010	
	0•(11001) = 00000
	1•(11001) = 11001

The space is closed under vector addition and scalar multiplication

Inner Product

$$\mathbf{x} \circ \mathbf{y} = \sum_{i=0}^{n-1} x_i \bullet y_i$$

(11001) \circ (10011) = 1 \circ 1 + 1 \circ 0 + 0 \circ 0 + 0 \circ 1 + 1 \circ 1
= 2
= 0 mod 2

11001 and 10011 are orthogonal

Vector Subspace

- A smaller vector space which is closed under vector addition and scalar multiplication
- Example: subspace of V₅

 $S = \begin{matrix} 00000 & 00111 \\ 00111 & + \underline{11011} \\ 11100 & 11100 \end{matrix}$

Basis

- A minimal number of linearly independent vectors (k) from the vector space that span the space
 - $\begin{bmatrix} 00111\\11100 \end{bmatrix} = 00000\\0 \cdot (00111) + 1 \cdot (11100) = 11100\\1 \cdot (00111) + 0 \cdot (11100) = 00111\\1 \cdot (00111) + 1 \cdot (11100) = 11011 \end{bmatrix}$
- Any vector in the space is a linear combination of basis vectors

Dual Space

• Set of vectors orthogonal to a vector space

S	S^{\perp}	
0000	0000	
0111	0011	
1100	1110	
1011	1101	
$ S \times S^{\perp} = V $		

Dual Space

• Set of vectors orthogonal to a vector space

$$S = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 \end{bmatrix}$$

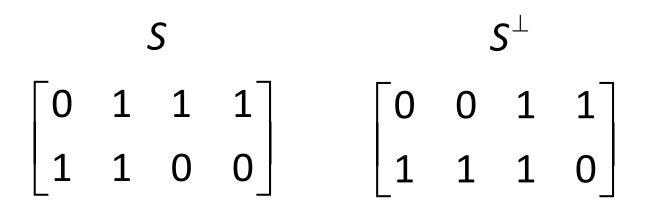

0 0 0 0 0

$$S^{\perp} = \begin{bmatrix} 1 & 0 & 1 & 0 & 1 \\ 1 & 1 & 0 & 1 \end{bmatrix}$$

0 1 1 0 1

Vector Space Dimensions

• If a basis has k elements then the vector space is said to have dimension k

 $\dim(S) + \dim(S^{\perp}) = \dim(V)$

Example

• For the subspace generated by the basis

$$\begin{bmatrix} 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 \end{bmatrix}$$

find a basis of the dual space

• In this case dim(V) = 5 and k = 2 so dim(S^{\perp}) = 5 - 2 = 3 $|S^{\perp}| = 2^3 = 8$

Example

• For the subspace generated by the basis

$$\begin{bmatrix} 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 \end{bmatrix}$$

a basis of the dual space is

$$\begin{bmatrix} 1 & 0 & 1 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 \end{bmatrix}$$

Self-Dual Spaces

$$S = S^{\perp}$$

• Example

S	S^{\perp}
0000	0000
1010	1010
0101	0101
1111	1111

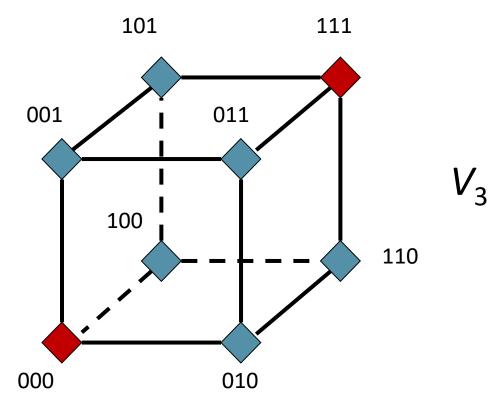

Binary Codes in Vector Spaces

Codewords can be considered as vectors in the vector space V_n of binary vectors of length n.

Definition A subset $C \subseteq V_n$ is a binary linear block code if $\mathbf{u} + \mathbf{v} \in C$ for all $\mathbf{u}, \mathbf{v} \in C$.

C is a k dimensional subspace of V_n .

Triple Repetition Code

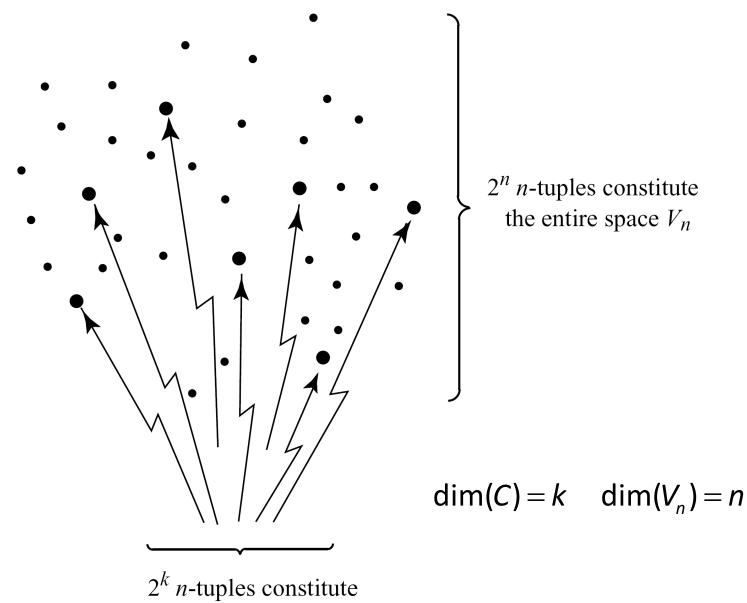

- The vector subspace is 000,111
- Basis [111]
- Dimension k = 1
- Length n = 3

Binary Linear Block Codes

- Binary linear code: mod 2 sum of any two codewords is a codeword
- Block code: codewords have a finite length *n*
- The number of codewords in a binary linear block code *C* is

$$|C| = M = 2^k$$

- Each codeword of length *n* represents *k* data bits
- The code rate is $R = \frac{\log_2 M}{n} = \frac{k}{n}$

the subspace of codewords

Which of the following binary codes is linear?

$$\begin{split} & C_1 = \{00, \, 01, \, 10, \, 11\} \\ & C_2 = \{000, \, 011, \, 101, \, 110\} \\ & C_3 = \{00000, \, 11110, \, 10011, \, 01101\} \\ & C_4 = \{101, \, 111, \, 011\} \\ & C_5 = \{0000, \, 001, \, 010, \, 011\} \\ & C_6 = \{0000, \, 1001, \, 0110, \, 1110\} \end{split}$$

Answer: C_1 , C_2 , C_3 and C_5

Generator (Basis) Matrices

• (3,1) repetition code

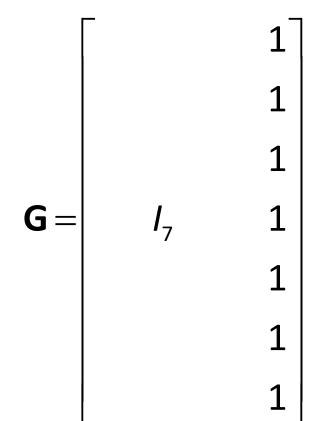

$$-n = 3, k = 1$$
 $\mathbf{G} = \begin{bmatrix} 1 & 1 & 1 \end{bmatrix}$

• c = mG

m = 0 c = 000m = 1 c = 111

Generator (Basis) Matrices

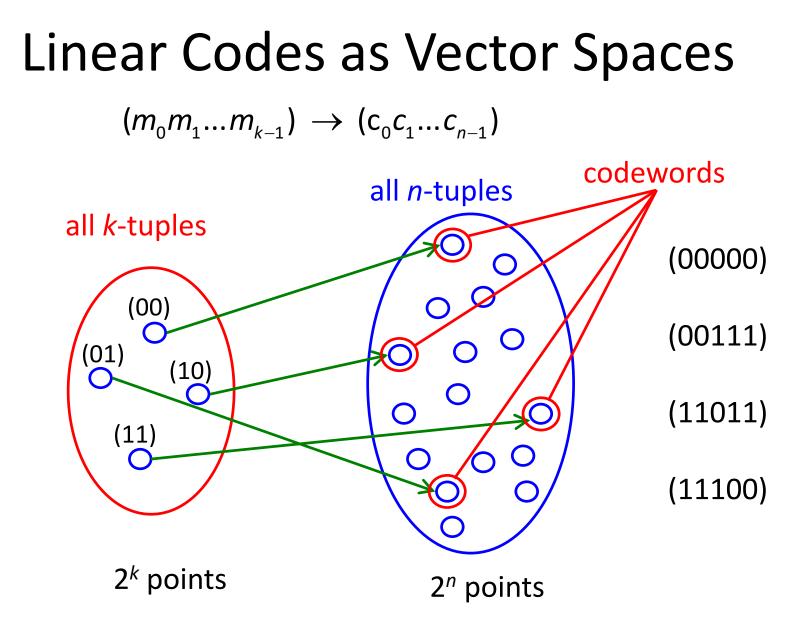

- (8,7) single parity check code
 - -n = 8, k = 7ASCII E = 1000101 c = 10001011 G = 1000111 c = 10001110

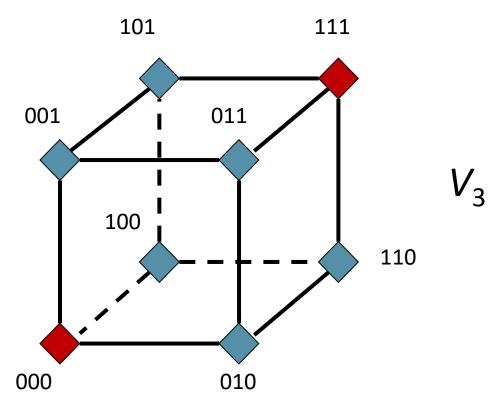

(5,2) Binary Linear Code

•
$$k \ge n$$
 Generator Matrix $\mathbf{G} = \begin{bmatrix} 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 \end{bmatrix} k = 2$
• $\mathbf{c} = \mathbf{m}\mathbf{G}$

Triple Repetition Code

Richard W. Hamming (1915-1998)

Hamming at Bell Labs

- The development of error correcting codes began in 1947 at Bell Laboratories
- Hamming had access to a mechanical relay computer on some weekends
- The computer employed an error detecting code, but with no operator on duty during weekends, the computer simply stopped or went on to the next problem when an error occurred

"Two weekends in a row I came in and found that all my stuff had been dumped and nothing was done." And so I said, "Damn it, if the machine can detect an error, why can't it locate the position of the error and correct it?"

Hamming Weight and Distance

- The concept of closeness of two codewords is formalized through the Hamming distance.
- Let **x** and **y** be two codewords in C

x = 00111 **y** = 11100

- The Hamming weight of a codeword is defined as the number of nonzero elements in the codeword w(x) = w(00111) = 3 w(y) = w(11100) = 3
- The Hamming distance between two codewords is defined as the number of places in which they differ

d(**x**,**y**) = d(00111,11100) = 4

Hamming Distances for Linear Codes

• For a binary linear code, the addition of any two codewords is another codeword

x + **y** = **z** 00111 + 11100 = 11011

• Thus

$$d(x, y) = w(x+y) = w(z) = w(11011) = 4$$

 Since we are concerned with the error correcting capability of a code *C*, an important criteria is the minimum Hamming distance d(*C*) or d_{min} between all pairs of codewords

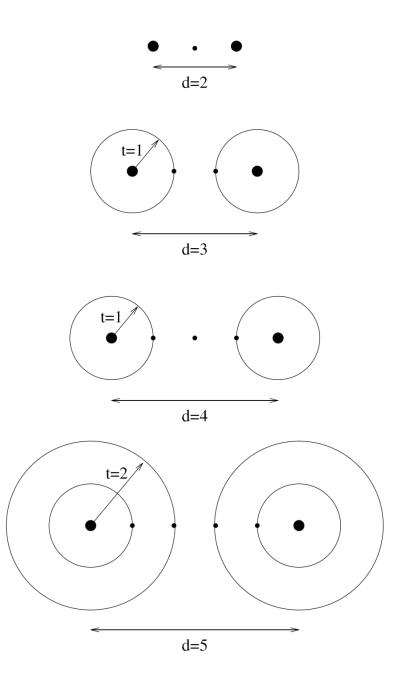

Minimum Hamming Distance

• The minimum Hamming distance of a code C is

 $d(C) = \min \{ d(\mathbf{x}, \mathbf{y}) \mid \mathbf{x}, \mathbf{y} \in C, \mathbf{x} \neq \mathbf{y} \}$ (also called d_{\min})

• For a linear code

 $d(C) = \min \{w(\mathbf{x}) \mid \mathbf{x} \in C, \, \mathbf{x} \neq 0\}$

Minimum Hamming Distance

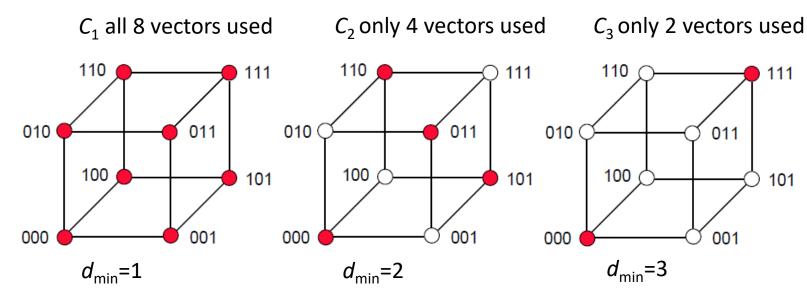

• A code C can detect up to v errors where

$$v = d(C)-1$$

• A code C can correct up to t errors where

$$t = \left\lfloor \frac{d(C) - 1}{2} \right\rfloor$$

Linear Codes of Length 3

Code rate *R* = 1 No error correction No error detection Code rate R = 2/3No error correction Single error detection Code rate R = 1/3Single error correction Double error detection

Notation and Examples

An (*n*,*k*,*d*) code *C* is a linear code where

- *n* is the length of the codewords
- *k* is the number of data bits represented by a codeword
- *d* is the minimum distance of *C*

$$d = d(C) = d_{\min}$$

Examples

 $C_1 = \{000, 100, 010, 001, 011, 101, 110, 111\} \text{ is a } (3,3,1) \text{ code}$ $C_2 = \{000, 011, 101, 110\} \text{ is a } (3,2,2) \text{ code}$ $C_3 = \{000, 111\} \text{ is a } (3,1,3) \text{ code}$

A good code has small *n*-*k* and large *d*.

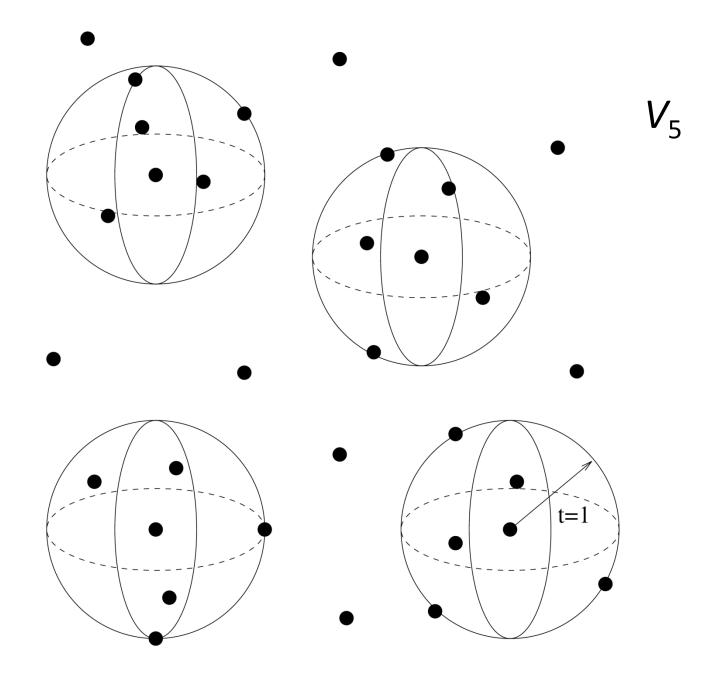

(5,2,3) Binary Linear Code

- c = mG m c w(c)
 - 00 00000 0
 - 01 11100 3
 - 10 00111 3
 - 11 11011 4

•
$$d_{\min} = d(C) = 3$$
 $t = \left\lfloor \frac{3-1}{2} \right\rfloor = 1$

$$\mathbf{G} = \begin{bmatrix} 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 \end{bmatrix}^2$$

5

Advantages of Linear Block Codes

- 1. The minimum distance d_{\min} is relatively easy to compute.
- 2. Linear codes can be simply characterized.
 - To specify a non-linear code usually requires all codewords to be listed.
 - To specify a linear (*n*,*k*) code it is enough to list *k* linearly independent codewords. These codewords form a basis for the vector space and the *k*×*n* matrix is called a generator matrix for *C*.

Examples
$$C_3 = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 1 & 1 \end{pmatrix}$$
 $\mathbf{G} = \begin{bmatrix} 1 & 1 & 1 \end{bmatrix}$ (3,1,3) code
 $C_2 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{pmatrix}$ $\mathbf{G} = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \end{bmatrix}$ (3,2,2) code
 $\begin{bmatrix} 1 & 1 & 0 \end{bmatrix}$

3. There are simple encoding and decoding procedures for linear codes.

Important Linear Block Codes

There are many classes of practical linear block codes:

- Hamming codes
- Cyclic codes (CRC codes)
- BCH codes
- Reed-Solomon codes
- Reed-Muller codes
- Product codes
- LDPC codes
- Turbo codes
- ..
